

ABSTRACT

A filter facility includes a filter device received in a container and having a housing for receiving a number of filter particles. The housing includes a peripheral partition extended into the chamber
5 from a bottom panel, and a plate disposed on top of the peripheral partition to form a compartment within the peripheral partition and the plate, and to form a peripheral space between the peripheral partition and a peripheral wall of the housing. The housing includes a number of apertures formed in the peripheral wall and the
10 peripheral partition and the plate to increase a flowing area of the fluid through the housing..
